# String manipulation with stringr:: CHEATSHEET

The **stringr** package provides a set of internally consistent tools for working with character strings, i.e. sequences of characters surrounded by quotation marks.

#### **Detect Matches**

str\_detect(string, pattern, negate = FALSE) Detect the presence of a pattern match in a string. Also str\_like(). str detect(fruit, "a")

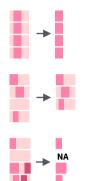

str\_starts(string, pattern, negate = FALSE) Detect the presence of a pattern match at the beginning of a string. Also **str\_ends()**. str starts(fruit, "a")

str\_which(string, pattern, negate = FALSE) Find the indexes of strings that contain a pattern match. str which(fruit, "a")

str\_locate(string, pattern) Locate the positions of pattern matches in a string. Also str\_locate\_all(). str locate(fruit, "a")

str\_count(string, pattern) Count the number of matches in a string. str count(fruit, "a")

#### **Subset Strings**

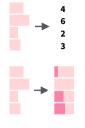

**str\_sub(**string, start = 1L, end = -1L**)** Extract substrings from a character vector. str sub(fruit, 1, 3); str sub(fruit, -2)

str\_subset(string, pattern, negate = FALSE) Return only the strings that contain a pattern match. str\_subset(fruit, "p")

str\_extract(string, pattern) Return the first pattern match found in each string, as a vector. Also **str\_extract\_all()** to return every pattern match. str\_extract(fruit, "[aeiou]")

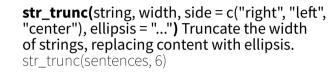

str\_match(string, pattern) Return the first pattern match found in each string, as a matrix with a column for each () group in pattern. Also str\_match\_all(). str match(sentences, "(althe) ([^ +])")

#### Manage Lengths

**str\_length(**string) The width of strings (i.e. number of code points, which generally equals the number of characters). str length(fruit)

str\_pad(string, width, side = c("left", "right", "both"), pad = " ") Pad strings to constant width. str\_pad(fruit, 17)

str\_squish(string) Trim whitespace from each end and collapse multiple spaces into single spaces. str squish(str pad(fruit, 17, "both"))

### **Mutate Strings**

A STRING

a string

A String

str\_sub() <- value. Replace substrings by</pre> identifying the substrings with str\_sub() and assigning into the results.

str sub(fruit, 1, 3) <- "str"

**str\_replace**(string, **pattern**, replacement) Replace the first matched pattern in each string. Also str\_remove().

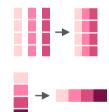

str\_replace(fruit, "p", "-")

str\_to\_upper(sentences)

str\_to\_upper(string, locale = "en")¹ Convert strings to upper case.

str\_to\_title(string, locale = "en")¹ Convert strings to title case. Also **str\_to\_sentence()**. str\_to\_title(sentences)

#### Join and Split

{xx} {yy}

str\_c(..., sep = "", collapse = NULL) Join multiple strings into a single string. str c(letters, LETTERS)

str\_flatten(string, collapse = "") Combines into a single string, separated by collapse. str flatten(fruit, ", ")

str\_dup(string, times) Repeat strings times times. Also **str\_unique()** to remove duplicates. str dup(fruit, times = 2)

**str\_split\_fixed(**string, **pattern**, n**)** Split a vector of strings into a matrix of substrings (splitting at occurrences of a pattern match). Also **str\_split()** to return a list of substrings and **str\_split\_i()** to return the ith substring. str split fixed(sentences, " ", n=3)

str\_glue(..., .sep = "", .envir = parent.frame()) Create a string from strings and {expressions} to evaluate. str\_glue("Pi is {pi}")

parent.frame(), .na = "NA") Use a data frame, list, or environment to create a string from strings and {expressions} to evaluate. str\_glue\_data(mtcars, "{rownames(mtcars)} has {hp} hp")

**str\_glue\_data(**.x, ..., .sep = "", .envir =

#### **Order Strings**

**str\_order(**x, decreasing = FALSE, na last = TRUE, locale = "en", numeric = FÁLSE, ...)1 Return the vector of indexes that sorts a character vector. fruit[str order(fruit)]

str\_sort(x, decreasing = FALSE, na last = TRUE, locale = "en", numeric = FALSE, ...)1 Sort a character vector. str\_sort(fruit)

## Helpers

TRUE FALSE

This is a long sentence. **▼** This is a long

**str\_conv**(string, encoding) Override the encoding of a string. str\_conv(fruit,"ISO-8859-1")

str\_view(string, pattern, match = NA) View HTML rendering of all regex matches. str\_view(sentences, "[aeiou]")

str\_equal(x, y, locale = "en", ignore\_case = FALSE, ...)<sup>1</sup> Determine if two strings are equivalent. str\_equal(c("a", "b"), c("a", "c"))

**str\_wrap(**string, width = 80, indent = 0, exdent = 0) Wrap strings into nicely formatted paragraphs. str\_wrap(sentences, 20)

<sup>1</sup> See **bit.ly/ISO639-1** for a complete list of locales.

#### **Need to Know**

Pattern arguments in stringr are interpreted as regular expressions after any special characters have been parsed.

In R, you write regular expressions as strings, sequences of characters surrounded by quotes ("") or single quotes(").

Some characters cannot be represented directly in an R string. These must be represented as **special characters**, sequences of characters that have a specific meaning., e.g.

Special Character	Represents
\\	\
\"	II .
\n	new line

Run?""" to see a complete list

Because of this, whenever a \ appears in a regular expression, you must write it as \\ in the string that represents the regular expression.

Use writeLines() to see how R views your string after all special characters have been parsed.

writeLines("\\.")

writeLines("\\ is a backslash") #\is a backslash

#### INTERPRETATION

Patterns in stringr are interpreted as regexs. To change this default, wrap the pattern in one of:

regex(pattern, ignore\_case = FALSE, multiline = FALSE, comments = FALSE, dotall = FALSE, ...) Modifies a regex to ignore cases, match end of lines as well of end of strings, allow R comments within regex's, and/or to have. match everything including \n.

str\_detect("I", regex("i", TRUE))

**fixed()** Matches raw bytes but will miss some characters that can be represented in multiple ways (fast). str\_detect("\u0130", fixed("i"))

**coll()** Matches raw bytes and will use locale specific collation rules to recognize characters that can be represented in multiple ways (slow). str\_detect("\u0130", coll("i", TRUE, locale = "tr"))

**boundary()** Matches boundaries between characters, line\_breaks, sentences, or words. str\_split(sentences, boundary("word"))

[:space:] [:blank:]

**LOOK AROUNDS** 

Regular Expressions - Regular expressions, or regexps, are a concise language for describing patterns in strings.

		9 00 0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
